

Grid Lines

In an $N \times M$ grid with each cell's dimension being 1×1 , there will be $(N+1) \times (M+1)$ cross points. Your task is to count the number of ways (S) of choosing K different points from these cross points such that all of them lie on a straight line and at least one of the cross points lies on the border.

Input Format

A single line containing 3 integers N , M & K separated by a single space.

Output Format

A single integer denoting the number of ways (S) modulo 1000000007

Constraints

$0 < N, M \leq 3000$

$2 \leq K \leq \max(N, M) + 1$

Sample Input

```
2 2 3
```

Sample Output

```
8
```

Explanation

If you imagine a grid of the first quadrant of the co-ordinate system. Then, we have, 8 such 3 points of which at least 1 point is on the borders.
