Digit Products

Let D(X) be a function that calculates the digit product of X in base ${\bf 10}$ without leading zeros. For instance:

$$D(0) = 0 \ D(234) = 2 \times 3 \times 4 = 24 \ D(104) = 1 \times 0 \times 4 = 0$$

You are given three positive integers A, B and K. Determine how many integers exist in the range [A, B] whose digit product equals K. Formally speaking, you are required to count the number of distinct integer solutions of X where $A \leqslant X \leqslant B$ and D(X) = K.

Input Format

The first line contains T, the number of test cases.

The next T lines each contain three positive integers: A, B and K, respectively.

Constraints

 $T \leqslant 10000$ $1 \leqslant A \leqslant B \leqslant 10^{100}$ $1 \leqslant K \leqslant 10^{18}$

Output Format

For each test case, print the following line:

Case X: Y

 \boldsymbol{X} is the test case number, starting at 1.

Y is the number of integers in the interval [A,B] whose digit product is equal to K.

Because Y can be a huge number, print it modulo $(10^9 + 7)$.

Sample Input

```
2
193
7376
```

Sample Output

```
Case 1: 1
Case 2: 3
```

Explanation

In the first test case, there is only one number (3) in the interval [1,9].

In the second test case, there are three numbers (16, 23, 32) in the interval [7, 37] whose digit product equals 6.
